

DP WAF & Load Balancer

NOC Training Quiz

15 short, simple multiple-choice questions on WAF and Load Balancer basics — what they are, what they do, and why they matter.

How to use this with Wayground (formerly Quizizz): open Wayground → Create → Quiz, then add each question below as a Multiple Choice question with 4 options, marking the correct answer as shown in the Answer Key at the end of this document. Alternatively, use Wayground's bulk import (Word/Excel template) and copy these questions/options/answers into that template.

Questions

Q1. What does WAF stand for?

- A. Web Application Firewall
- B. Wide Area Firewall
- C. Web Access Filter
- D. Wireless Application Function

Q2. Where does a WAF sit?

- A. Behind the database
- B. In front of the web application
- C. Inside the user's browser
- D. On the user's phone

Q3. What layer does a WAF mainly protect?

- A. The application layer (HTTP/HTTPS)
- B. The physical cabling layer
- C. The power supply
- D. The office network only

Q4. How is a WAF different from a normal firewall?

- A. It's slower
- B. It reads the actual content of web requests, not just IP/port
- C. It only blocks emails
- D. It has no difference

Q5. What is the main job of a WAF?

- A. Speed up the website
- B. Detect and block malicious web requests
- C. Store website backups
- D. Design the website layout

Q6. What is a Load Balancer used for?

- A. Encrypting passwords
- B. Spreading traffic across multiple servers
- C. Designing web pages
- D. Sending emails

Q7. Why does a website need a load balancer?

- A. To make the logo bigger
- B. So one server doesn't get overloaded by too much traffic
- C. To change the website's colors
- D. To block all traffic

Q8. What happens if a single server gets more traffic than it can handle?

- A. Nothing changes
- B. It can slow down or stop responding (overloaded)
- C. It automatically gets faster
- D. It deletes old files

Q9. Which of these is a load balancing method?

- A. Round Robin
- B. Copy Paste
- C. Screen Sharing
- D. Auto Save

Q10. What does "Least Connections" load balancing do?

- A. Sends traffic to the server with the fewest active connections
- B. Sends traffic to a random server
- C. Blocks all connections
- D. Only uses one server forever

Q11. What does "IP Hash" load balancing do?

- A. Deletes the visitor's IP address
- B. Always sends the same visitor to the same server
- C. Blocks visitors from certain countries

D. Changes the visitor's IP address

Q12. With a load balancer running several servers, what happens if one server is full?

- A. The whole website goes down
- B. New visitors can be sent to a different server instead
- C. The server explodes
- D. Nothing, visitors just wait forever

Q13. What is DDoS protection mainly designed to stop?

- A. Slow typing
- B. A flood of traffic trying to overwhelm a server
- C. Spelling mistakes on a website
- D. Users forgetting their password

Q14. How can suspicious traffic be identified for blocking?

- A. By checking which browser theme they use
- B. By watching for unusual traffic patterns, e.g. from a specific IP address
- C. By asking the visitor nicely
- D. It cannot be identified at all

Q15. Why do WAF and Load Balancer work well together?

- A. They don't work together
- B. One blocks bad requests, the other spreads good traffic evenly — together they keep a site safe and available
- C. They cancel each other out
- D. Only one can be used at a time

Answer Key & Explanations

Q1. Correct answer: A. Web Application Firewall

A WAF is a Web Application Firewall — it protects web apps specifically.

Q2. Correct answer: B. In front of the web application

A WAF sits in front of the app, checking traffic before it reaches the server.

Q3. Correct answer: A. The application layer (HTTP/HTTPS)

A WAF inspects HTTP/HTTPS traffic at the application layer — where web attacks happen.

Q4. Correct answer: B. It reads the actual content of web requests, not just IP/port

A normal firewall checks IP/port; a WAF reads the request content itself.

Q5. Correct answer: B. Detect and block malicious web requests

A WAF's core job is spotting bad requests and blocking them before the app sees them.

Q6. Correct answer: B. Spreading traffic across multiple servers

A load balancer distributes incoming traffic across several servers.

Q7. Correct answer: B. So one server doesn't get overloaded by too much traffic

One server has limited capacity; a load balancer spreads the load so it doesn't overload.

Q8. Correct answer: B. It can slow down or stop responding (overloaded)

Too much traffic on one server causes slowdowns or errors like "service unavailable."

Q9. Correct answer: A. Round Robin

Round Robin is a common method: requests are sent to servers in turn, one after another.

Q10. Correct answer: A. Sends traffic to the server with the fewest active connections

Least Connections picks whichever server currently has the least active load.

Q11. Correct answer: B. Always sends the same visitor to the same server

IP Hash keeps a visitor going to the same server each time, using their IP address.

Q12. Correct answer: B. New visitors can be sent to a different server instead

That's the whole point of load balancing — traffic moves to a server that has room.

Q13. Correct answer: B. A flood of traffic trying to overwhelm a server

DDoS protection defends against large floods of traffic meant to knock a service offline.

Q14. Correct answer: B. By watching for unusual traffic patterns, e.g. from a specific IP address

Systems watch traffic patterns (like one IP sending way too many requests) to flag abuse.

Q15. Correct answer: B. One blocks bad requests, the other spreads good traffic evenly — together they keep a site safe and available

WAF = security (blocking bad traffic). Load Balancer = availability (handling good traffic well). Together they cover both.
